

S8 10m winds

Tonight, noticed long periods of wind outages at S8. The rserial output show that these period have data values of 999.99 with an error code=04 (the manual says that the value of this code provides "no useful information to the user!"). However, I also see reasonable data interspersed with the bad periods. I suspect a bird is roosting in the array (despite Dan's heroic effort at making bird spikes) and that this problem will go away. Just to do something, I ddh/dup and eio 6 0/1, to no effect.
